

WeekWeave

Calendar Feed Integration & Conflict Review

Independent software project | Owner: Ismail Habib | Created September 2026

Actual application capture. Any example records are labeled verification inputs.

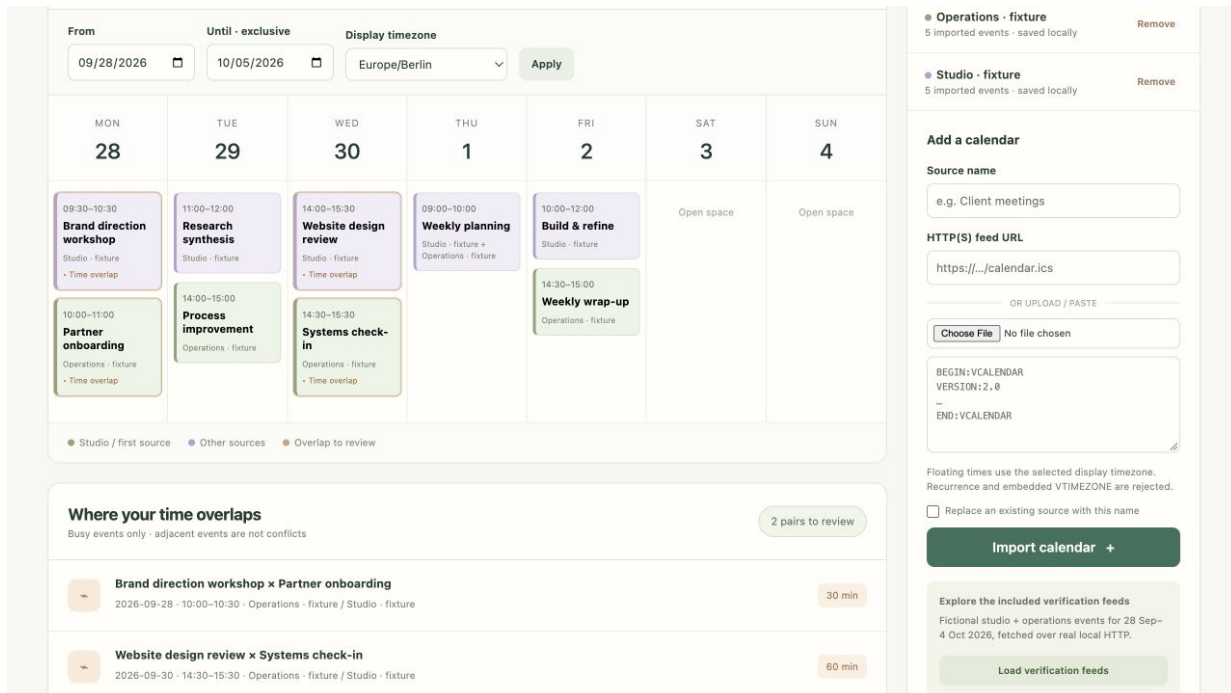

The problem

Separate calendars obscure duplicate events, timezone differences and overlapping busy periods.

What the project delivers

- ICS upload, paste or real HTTP feed import
- IANA timezone normalization and DST validation
- Exact duplicate merging and busy-event overlap review
- Consolidated ICS and spreadsheet-safe conflict CSV export

Built to be inspected.

Actual merged calendar events and two computed overlap intervals, with source labels and import controls.

What was verified

13 automated tests passed. Actual HTTP verification feeds yield 9 merged events from 10 source events, with 1 duplicate and 2 overlapping pairs.

How it works

ICS files / HTTP feeds to Validate whole source to Normalize & persist to Merge exact matches to Review overlaps to ICS / CSV export

Current scope

New independent project with fictional verification calendars. Documented RFC 5545 subset: recurrence and embedded VTIMEZONE/VALARM rejected. Local single-user service; no OAuth, source writeback, automatic refresh or public deployment.

Included: source code, setup guide, tests, screenshots, editable case study and Malt copy.
